

Conclusion

Team ID	SWUID2026136950
Project Name	Automated Network Request Management in ServiceNow

1. Project

The Automated Network Request Management in ServiceNow project successfully delivers an end-to-end automated solution for handling network requests in an enterprise environment. The system was built as a scoped application called Network Request Management (x_2128291_networ_0) and includes 15 integrated features that cover the entire lifecycle — from submission and approval to task fulfillment, closure, and feedback collection. The solution eliminates manual coordination, enforces governance through automated approvals, and provides full visibility to all stakeholders through reports and dashboards.

2. Key Achievements

The project achieved several key milestones. A custom table was created to store all request data with seven custom fields. Three dynamic UI Policies were implemented to control form field visibility based on request type. A Service Catalog item was built with five variables to capture complete request details. A Flow Designer workflow with seven actions was configured to automate the entire lifecycle, including approval routing, task creation, task tracking, and auto-closure. Eight email notifications were created to keep all stakeholders informed at every stage. An SLA definition with a four-hour target was implemented to track approval time. SLA breach notifications, approval reminders, and auto-escalation were configured to ensure timely action. Priority levels were added to enable fast-tracking of urgent requests. Three reports and a management dashboard were built to provide real-time visibility. A feedback survey was deployed to collect requester feedback after completion. Finally, the entire solution was packaged into an update set for deployment.

3. End-to-End Workflow Success

The end-to-end workflow was tested successfully. A network request was submitted through the Service Portal, the flow triggered automatically, the approval was routed to the appropriate group, the task was auto-created and assigned to the Network Team, the engineer completed the work and closed the task, and the Requested Item was automatically closed. All seven actions in the flow executed successfully, and all five email notifications were sent. The SLA timer tracked the approval time accurately, and the dashboard updated in real time. This confirmed that the automation works exactly as designed.

4. Challenges Faced and Resolved

Several challenges were encountered during the project. Initially, the flow trigger was not firing when a request was submitted — this was resolved by changing the trigger table to sc_req_item. The UI Policies were not hiding mandatory fields correctly — this was fixed by adjusting the execution order in the client script. Duplicate approval notifications were discovered — these were cleaned up by

identifying and deleting the duplicate records. The global flow could not reference the group from the scoped application — this was resolved by creating a new group called Network Approvers Global in the global scope. The escalation flow was blocking task creation — this was resolved by restructuring the flow so that escalation runs in parallel instead of blocking the main path. Each challenge provided valuable learning and strengthened the final solution.

5. Learning Outcomes

Through this project, I gained hands-on experience with multiple ServiceNow capabilities. I learned how to build a scoped application from scratch, how to create custom tables and fields, how to implement dynamic UI Policies for smart form behavior, how to build a Flow Designer workflow with multiple actions and conditions, how to configure email notifications across the lifecycle, how to define and track SLAs, how to implement role-based access control with ACLs and groups, how to create reports and dashboards, how to design and deploy surveys, and how to manage update sets for deployment. I also learned the importance of testing at every stage and the value of debugging when things don't work as expected.

6. Business Value

The business value of this project is significant. Manual coordination effort is reduced by approximately 30 minutes per request. Fulfillment time is reduced from 3-5 days to under 1 day. Audit preparation time is reduced by up to 80% because all approvals and changes are logged automatically. The standardized process eliminates errors caused by incomplete or unclear requests. The SLA tracking ensures accountability and timely approvals. The escalation and reminder features prevent requests from getting stuck. The reporting and dashboard provide management with real-time visibility for better decision-making. The feedback survey enables continuous improvement of the service.

7. Social Impact

The social impact of this project is also notable. It reduces the manual workload for IT teams, improving their work-life balance. It provides transparency and accountability, which builds trust between IT and the rest of the organization. It ensures compliance with audit requirements, which is critical in regulated industries such as finance, healthcare, and government. It improves the overall employee experience by making network requests faster and more predictable.

8. Future Scope

While the current solution is comprehensive, there are several opportunities for future enhancement. Multi-level approvals could be added for high-risk requests such as firewall changes. Integration with actual network devices could enable automatic configuration. Virtual Agent could be used for natural language request intake. The Service Portal could be optimized for mobile devices. Advanced analytics with Performance Analytics could provide trend analysis and forecasting. Bulk request submission could be supported for multiple devices. A knowledge base integration could help users self-serve common requests. Email preference centers could give users control over which notifications they receive. Integration with change management could streamline firewall changes.

Finally, the solution could be extended to other IT request types beyond network, such as server access, database access, and application access.

9. Final Reflection

In conclusion, this project demonstrates how ServiceNow can be used to transform a manual, error-prone process into a fully automated, auditable, and efficient system. The solution is scalable, secure, and aligned with industry best practices. It delivers measurable value in terms of time savings, cost savings, compliance, and user satisfaction. The project has given me valuable hands-on experience and a strong foundation in ServiceNow application development. I am confident that the skills and knowledge gained will be valuable in my future career.
