

1. Introduction

Team ID	SWUID2026136950
Project Name	Automated Network Request Management in ServiceNow

1.1 Project Overview

The Automated Network Request Management in ServiceNow is a fully automated, enterprise-grade solution built on the ServiceNow platform to streamline how network requests are submitted, approved, fulfilled, and closed within an organization. In most enterprises, network requests are handled manually through emails, chat messages, and phone calls. This leads to delays, lack of standardization, no audit trail, and poor visibility for both requesters and IT management. The manual process often requires multiple back-and-forth communications, making it slow and error-prone.

This project addresses these challenges by providing a single, standardized, and automated system for network request management. It is built as a scoped application called Network Request Management (x_2128291_networ_0) and includes 15 integrated features that cover the entire lifecycle of a network request.

The solution begins with a Service Catalog item called Network Request, where users can submit requests for network access, firewall configuration, or device configuration. The catalog item has five variables - Request Type, Access Level, Device, Port, and Business Justification -ensuring complete data capture. Three dynamic UI Policies control form field visibility based on the selected request type, making the form smart and context-aware.

Once a request is submitted, a Flow Designer workflow with seven actions triggers automatically. It sends an approval request to the Network Approvers group, waits for the decision, and once approved, creates a Catalog Task assigned to the Network Team. The flow then waits for the task to be closed by the engineer and finally updates the Requested Item to Closed Complete. This entire process happens without any manual intervention.

Eight email notifications keep all stakeholders informed at every stage — submission, approval request, approval decision, completion, SLA breach, approval reminder, escalation, and feedback request. A four-hour SLA tracks approval time, with automatic breach notifications and escalation to management if the approval is delayed beyond two hours.

Role-based access control is enforced through three roles (requester, approver, engineer) and four groups (Network Requesters, Network Approvers Global, Network Team, Network Escalation Managers). Access Control Lists (ACLs) ensure that only authorized users can read, create, or write records.

The system also includes three reports (Request Volume by State, Task Performance, SLA Compliance) and a management dashboard that provides real-time visibility into request metrics. A post-completion feedback survey collects requester feedback to enable continuous improvement.

The solution is designed to be scalable, secure, and aligned with ServiceNow best practices. It eliminates manual coordination, enforces governance through automated approvals, provides full

audit trails, and improves both IT efficiency and user satisfaction. All components are packaged into an update set for easy deployment across instances.

1.2 Purpose

The primary purpose of this project is to automate the entire network request management lifecycle in ServiceNow, eliminating the inefficiencies of manual, email-based processes. By doing so, the project aims to achieve the following objectives:

1. Standardize the Request Process

To replace the inconsistent methods of submitting network requests (email, chat, phone) with a single, standardized Service Catalog form that captures all required information in a structured manner.

2. Automate Approval Routing

To route network requests automatically to the appropriate approvers based on request type and priority, eliminating the need for manual follow-up and ensuring timely decisions.

3. Automate Task Creation and Assignment

To automatically create fulfillment tasks and assign them to the Network Team as soon as a request is approved, removing the manual handoff between approval and fulfillment.

4. Provide Real-Time Visibility

To give requesters, approvers, engineers, and managers real-time visibility into the status of every request through emails, reports, and dashboards.

5. Ensure Governance and Compliance

To maintain a complete audit trail of every action, approval, and state change, ensuring compliance with internal policies and external regulations.

6. Track and Enforce SLAs

To define and monitor a four-hour SLA for approvals, with automatic breach notifications and escalation to management when SLAs are at risk.

7. Enable Priority-Based Handling

To allow requests to be marked as Critical, High, Medium, or Low, ensuring that urgent requests receive faster attention.

8. Reduce Manual Effort

To reduce the manual coordination workload for IT teams by approximately 30 minutes per request, freeing them to focus on higher-value work.

9. Improve User Experience

To provide a smooth, transparent, and predictable experience for employees submitting network requests, with clear communication at every stage.

10. Enable Continuous Improvement

To collect feedback from requesters after completion and use that feedback to improve the network request service over time.

11. Support Scalability

To build the solution on ServiceNow's cloud platform, ensuring that it can scale to handle hundreds of requests per day without additional infrastructure or manual overhead.

12. Provide a Foundation for Future Enhancements

To create a modular, extensible solution that can be enhanced with features such as multi-level approvals, mobile access, Virtual Agent integration, and advanced analytics.

By achieving these objectives, the project aims to transform a slow, manual, and error-prone process into a fast, automated, and reliable system that delivers measurable value to both IT and the wider organization.
